The linguistics of signifying time: the human gesture as clock

(Washington, DC) – A new scientific study documenting the linguistic practices of the Northwestern Amazonian peoples uncovers an unusual method of communicating the human concept of time. The study, “Modally hybrid grammar? Celestial pointing for time-of-day reference in Nheengatú”, by Simeon Floyd of the Max Planck Institute for Psycholinguistics in the Netherlands, was published in the March, 2016 issue of the scholarly journal *Language*. A pre-print version of the article may be found at: http://www.linguisticsociety.org/sites/default/files/archived-documents/Lg_92.1_Floyd.pdf.

The article examines how the Nheengatú language includes both auditory and visual components to express the time of day, even though it does not have any numerical or written system for telling time. Speakers of Nheengatú talk about time of day by pointing at where the sun would be in the sky at that particular time. For speakers of Nheengatú, this is the same as saying things like "nine o'clock" in English. This practice is notable because many linguists have assumed that users of auditory languages would not also develop visual language like that seen in sign languages, but this phenomenon shows that this is not necessarily the case.

When humans conceive of grammar we might think of categories like nouns, verbs, adjectives and adverbs that people communicate by vocalizing. Research with speakers of Nheengatú reveals that this is not always the case, however, and that in some languages it is possible to communicate some of these concepts, by combining movements of the hands and body with speech in systematic ways. In this case visual elements play a role comparable to that usually played by spoken adverbs, adding information about time to the verbs they occur with.

These Nheengatú physical expressions are the type of visual language we expect to see in sign languages, but for spoken languages it is often assumed that all of the words should be audible, not visual, and that the gestures that come along with speech only give extra, peripheral meanings, and not the main information about the topic of talk. These practices seen in small communities in the Amazon have the potential to change how scientists think about the modalities in which language is expressed, because they show that humans don't necessarily have to choose between speaking and signing and are capable of doing both simultaneously.

Nheengatú time reference is just one of the types of combinations of spoken and visual language that some linguists are beginning to suspect may be more common than is currently known; since historically many languages have been studied only based on written words and audio recordings, future scientific studies of video recordings may find new and unexpected types combinations of spoken and visual language that may have been previously invisible.

#####

The Linguistic Society of America (LSA) publishes the peer-reviewed journal, Language, four times per year. The LSA is the largest national professional society representing the field of linguistics. Its mission is to advance the scientific study of language.
